In engineering applications competing risks arise when analyzing series systems. Classical competing risks deal with the modeling of the probability of failure in the observed system (crude probabilities) or in systems with some causes of failure removed (net or partial crude probabilities).

In failure-time settings, a competing risk event is any event that makes it impossible for the event of interest to occur. For example, cardiovascular disease death is a competing event for prostate cancer death because an individual cannot die of prostate cancer once he has died of cardiovascular disease. 1. State or recognize examples of competing risks survival data. 2. Given competing risks data, outline the steps needed to analyze such data using separate Cox models. 3. Given computer output from the analysis of competing risk data, carry out an analysis to assess the effects of explanatory variables on one or more of the competing risks. 4.

In contrast, a classical approach to competing risks is via latent failure times as briefly summarized by Kalbfleisch and Prentice<sup>12</sup> (see Section 8.2.4). In that approach one imagines the existence of random variables,  $L_1$ ,  $L_2$ , representing time to failure from Cause 1 and time to failure from Cause 2, respectively.

Bone marrow transplant (BMT) is a standard treatment for acute leukemia. Klein and Moeschberger present a set of BMT data for 137 patients, grouped into three risk categories based on their status at the time of transplantation: acute lymphoblastic leukemia (ALL), acute myelocytic leukemia (AML) low-risk, and AML high-risk. During the follow-up period, some patients might relapse or some

Under the classical competing risks framework, a subject may be simultaneously exposed to several distinct events, but may eventually only fail from one of these. In such settings, the occurrence of a specific failure type would preclude the competing events from being observed.

1. Introduction. Survival analysis with competing risks data is very common in the field of medical studies and now gaining more attention and interest in many research areas , , . For instance, a physician may be interested in time to death of a particular disease, but the patient can die from another competing disease(s) that may be potentially dependent or independent of disease of interest .

Throughout this paper, we assume constant hazards. In the simulation studies we simulated 100 data sets with 10000 individuals to see if the methods provide accurate results on average. For the simulation of time-independent covariates, we have a classical competing risks setting with two risk factor groups ('pneumonia on admission' yes or no).

The relevance of competing risks in medical research is highlighted by methodological papers in various medical fields. We mention [ 3 - 5] as recent examples. A classical statistics textbook account has been given in the first edition of [ 6] in 1980, and a definite mathematical treatment based on counting processes is included in [ 7 ].
