Signals and Systems A continuous-time signal is a function of time, for example written x(t), that we assume is real-valued and defined for all t, -∞ < t < ∞. A continuous-time system accepts an input signal, x(t), and produces an output signal, y(t). A system is often represented as an operator "S" in the form y(t) = S [x(t)]. LTI Systems A linear continuous-time system obeys the following ...

The modification of linear systems and signals courses has gone in two directions: (a) teaching it at the sophomore level, as the course on signals and time-frequency transforms, with little emphasis on system dynamics (in general, sophomore students do not have sufficient knowledge of differential equations); (b) teaching it as a junior (or even senior) level course with emphasis on system ...

Linear Dynamic Systems and Signals by Zoran Gajic

Signals and systems is an aspect of electrical engineering that applies mathematical concepts to the creation of product design, such as cell phones and automobile cruise control systems. Absorbing the core concepts of signals and systems requires a firm grasp on their properties and classifications; a solid knowledge of algebra, trigonometry, complex arithmetic, calculus of [...]

Requirements for Linear Systems. To determine if a system is linear, we need to answer the following question: When an input signal is applied to the system, does the output response exhibit homogeneity and additivity? If a system is both homogeneous and additive, it is a linear system. Homogeneity. Let's say we apply an input signal x(t) to ...

What is a Linear System? - Technical Articles

In system analysis, among other fields of study, a linear time-invariant system (or "LTI system") is a system that produces an output signal from any input signal subject to the constraints of linearity and time-invariance; these terms are briefly defined below. These properties apply (exactly or approximately) to many important physical systems, in which case the response y(t) of the system to ...

2 LINEAR SYSTEMS 3 2.2 Time-Invariant Systems A dynamic system is time-invariant if shifting the input on the time axis leads to an equivalent shifting of the output along the time axis, with no other changes. In other words, a time-invariant system maps a given input trajectory u(t) no matter when it occurs: y(t – τ) = F [u(t – τ)].

LTI Systems Summary. Two very important and useful properties of systems have just been described in detail. The first of these, linearity, allows us the knowledge that a sum of input signals produces an output signal that is the summed original output signals and that a scaled input signal produces an output signal scaled from the original output signal.
